

Tornqvist indexing in R

Tqtools package

Mike Jadoo / Economist

Peter B. Meyer / Research Economist

Office of Productivity and Technology,

U.S. Bureau of Labor Statistics

Conference of Statistical Practice

New Orleans, 2/15/2019

Motivation

Provide routines to help individuals to properly aggregate indices using the Tornqvist method.

Vocabulary

Productivity:

- Labor

- Multifactor

NAICS

Nonfarm business sector

Cost of production

Measures

Index :

- Price

- Quantity

Vocabulary

Productivity: a measure of efficiency which compares the amount of goods and services produced (output) with the amount of inputs used.

Vocabulary

$$\text{Labor Productivity} = \frac{\textit{Output}}{\textit{Hours Worked}}$$

Multifactor Productivity

$$= \frac{\textit{Output}}{\textit{Combination of Labor and Capital Inputs}}$$

Vocabulary

NAICS: North American Industry Classification System is the standard used by Federal statistical agencies for classifying business establishments

-Sector: 2-digit

-Subsector: 3-digit

-Industry group- 4-digit

Level	NAICS CODE	Description
Sector	44-45	Retail Trade
Subsector	441	Motor Vehicle and Parts dealer
Industry Group	4412	Other Motor Vehicle Dealers

Vocabulary

Nonfarm business sector: includes about 75% of U.S. economy. It excludes general government, farms, and household work.

Vocabulary

Cost of production: cost of producing an item in an industry in current dollars. These can be used as weights in our Index formula.

Measures: Our quantification of a particular concept measured over time

Vocabulary

Index: a statistical representation of a level over time for a particular measure using a base year.

Price index: measurement of price movements in a numerical series

Quantity index: represents a real measure of a particular input or output.

$$\text{Cost} = \text{Price} * \text{Quantity} \text{ and } \text{Price} = \frac{\text{Cost}}{\text{Quantity}}$$

Agenda

- ❑-Overview of productivity measures
- ❑-Common Index formulas
- ❑-How Tornqvist is used
- ❑-Demonstrations
 1. Information capital measure
 2. Manufacturing sector aggregation

Overview of productivity measures

Why is Productivity Growth Important?

- Enables higher living standards
- Source of potential gains in national income
- Key to competitiveness
- Used in employment projections

Productivity

Measure

NAICS industry coverage

Press release

■ Quarterly Labor Productivity

- Business and Nonfarm Business Sectors
- Manufacturing Sectors
- Nonfinancial Corporations

NEWS RELEASE
BUREAU OF LABOR STATISTICS
U.S. DEPARTMENT OF COMMERCE

Transmission of material in this release is embargoed until 8:30 a.m. EDT on Wednesday, March 9, 2018.

Media contact: (202) 491-2002 • PressOffice@bls.gov

PRODUCTIVITY AND COSTS
Fourth Quarter and Annual Average 2017, Revised

Nonfarm business sector labor productivity growth was revised to 0.6 percent in the fourth quarter of 2017, the 1.6th revision of labor productivity reported today, as output increased 1.2 percent and hours worked increased 1.2 percent. Last quarterly growth change in the private and nonfinancial business sectors was 0.5 percent, following a 1.2 percent increase in output and a 1.7 percent increase in hours worked. Over the last 12 months, annual average productivity increased 1.2 percent from 2016 to 2017. (See Table 1.)

Labor productivity, or output per hour, is calculated by dividing an index of real output by an index of hours worked by all persons, including employees, proprietors, and unpaid family workers.

Chart 1. Labor productivity-nonfarm business, private sector

Chart 2. Labor productivity-nonfarm business, private sector

Key labor news for the nonfarm business sector included a 1.2 percent rise in the fourth quarter of 2017, and increased 1.7 percent over the last four quarters. (See chart 2 and tables A1 and 2.)

■ Annual Labor Productivity

- Manufacturing and Mining Industries
- Services Industries
- Wholesale and Retail Trade Industries

NEWS RELEASE
BUREAU OF LABOR STATISTICS
U.S. DEPARTMENT OF COMMERCE

For release 10:00 a.m. (EDT) Thursday, August 2, 2017

Technical information: (202) 491-2000 • productivity@bls.gov • www.bls.gov/ipc
Media Contact: (202) 491-2002 • PressOffice@bls.gov

PRODUCTIVITY AND COSTS BY INDUSTRY, WHOLESALE TRADE, RETAIL TRADE, AND FOOD SERVICE AND DRINKING PLACES

Labor productivity rose 1.2 percent in manufacturing, a 1.6 percent annual rate, and 1.3 percent in the nonfinancial business sector. Labor productivity in the services industries rose 1.2 percent, and in the food service and drinking places and retail trade sectors. (See Table 1.)

Four industries made up 2016 productivity growth, and began recorded all treatment at a slower rate than in 2015. In retail trade, the productivity measure was revised to show a 1.2 percent increase in output and a 1.9 percent increase in hours worked in 2015. Productivity growth in food services and drinking places in 2016 was adjusted from that of 2015 as output increased at a slower rate.

Chart 1. Productivity change in the largest (by government) 4-digit wholesale trade, retail trade, and food service and drinking places establishments, 2016

■ Annual Multifactor Productivity

- Private Business
- Nonfarm Business
- Manufacturing
- 60 3-digit NAICS industries

NEWS RELEASE
BUREAU OF LABOR STATISTICS
U.S. DEPARTMENT OF COMMERCE

For release 10:00 a.m. (EDT) March 30, 2017

Technical information: (202) 491-2000 • ipc@bls.gov • www.bls.gov/ipc
Media contact: (202) 491-2002 • PressOffice@bls.gov

MULTIFACTOR PRODUCTIVITY TRENDS—2016

Private nonfarm business sector multifactor productivity decreased at a 1.2 percent annual rate in 2016, the 1.6th revision of labor productivity reported today. (See chart 1, table A.) The 2016 decline reflected a 1.2 percent increase in output and a 1.6 percent increase in the combined input of capital and labor. Capital services grew by 1.8 percent and labor input rose by 1.6 percent in the combined effect of hours worked and labor productivity growth over 2015. This was the first decline in multifactor productivity growth since 2009. (See table 1.)

Multifactor productivity is calculated by dividing an index of real output by an index of combined units of labor, capital, and energy services. Multifactor productivity for the nonfarm sector includes the influence of capital services and ability in labor productivity of the nonfarm business sector. In the private nonfarm sector, the release of productivity statistics, see the Technical Notes for additional information.

Private nonfarm business sector multifactor productivity decreased at a 0.1 percent annual rate in 2016. A 1.6 percent increase in output and a 1.6 percent decline in the combined input of capital and labor resulted in the multifactor productivity decline in 2016. (See table 2, table A.)

Chart 1. Multifactor productivity, labor productivity, and output per unit of capital services in the private nonfarm business sector for the 1987-2016 period

Overview of productivity measures

Common Index formulas

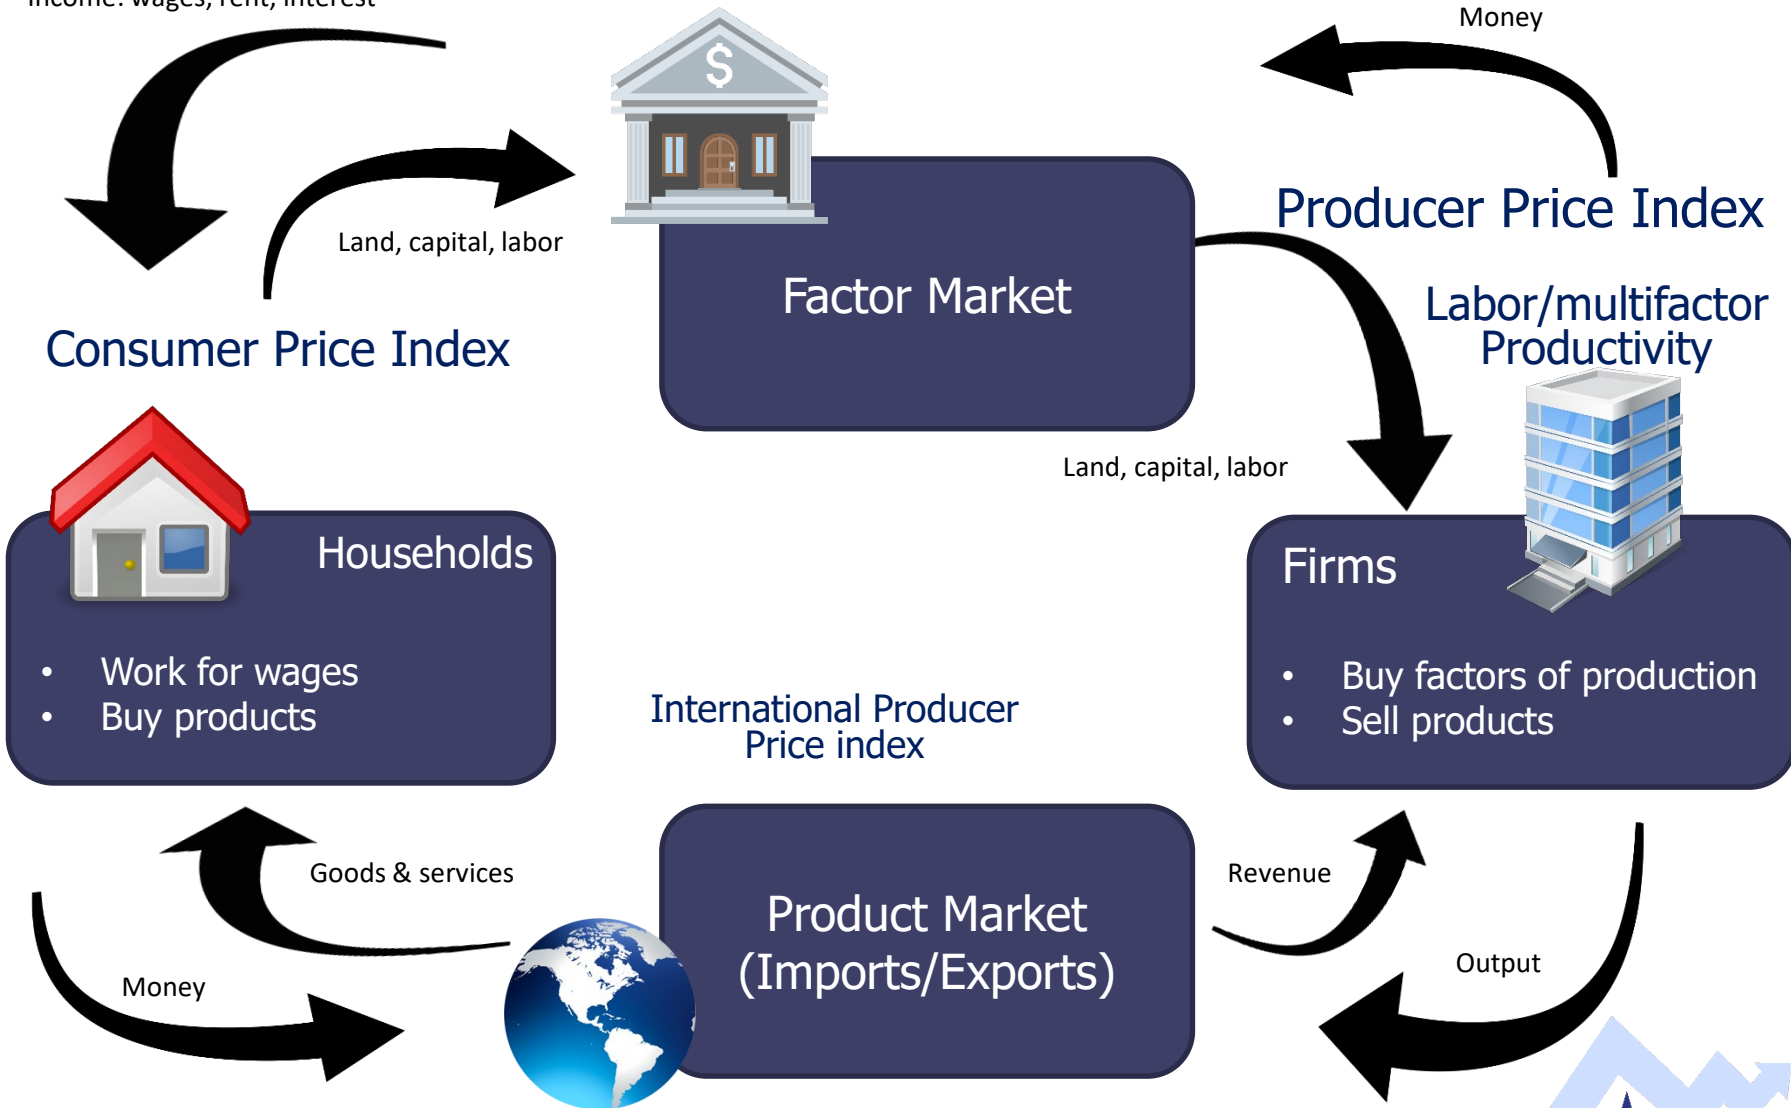

Advantages of Using Indices

- Detailed input data have different units, but the indexes have growth rates, which can be compared.
- The relevant production theory is rearranged to address growth rates only.
- A flexible index function is a good approximation to any smooth production function.
 - ▶ Tornqvist index matches the translog production function
- Therefore it is not necessary to specify a production function, and BLS Productivity Office does not pick one.
 - ▶ Capital, labor, and intermediate inputs are computed in indexes

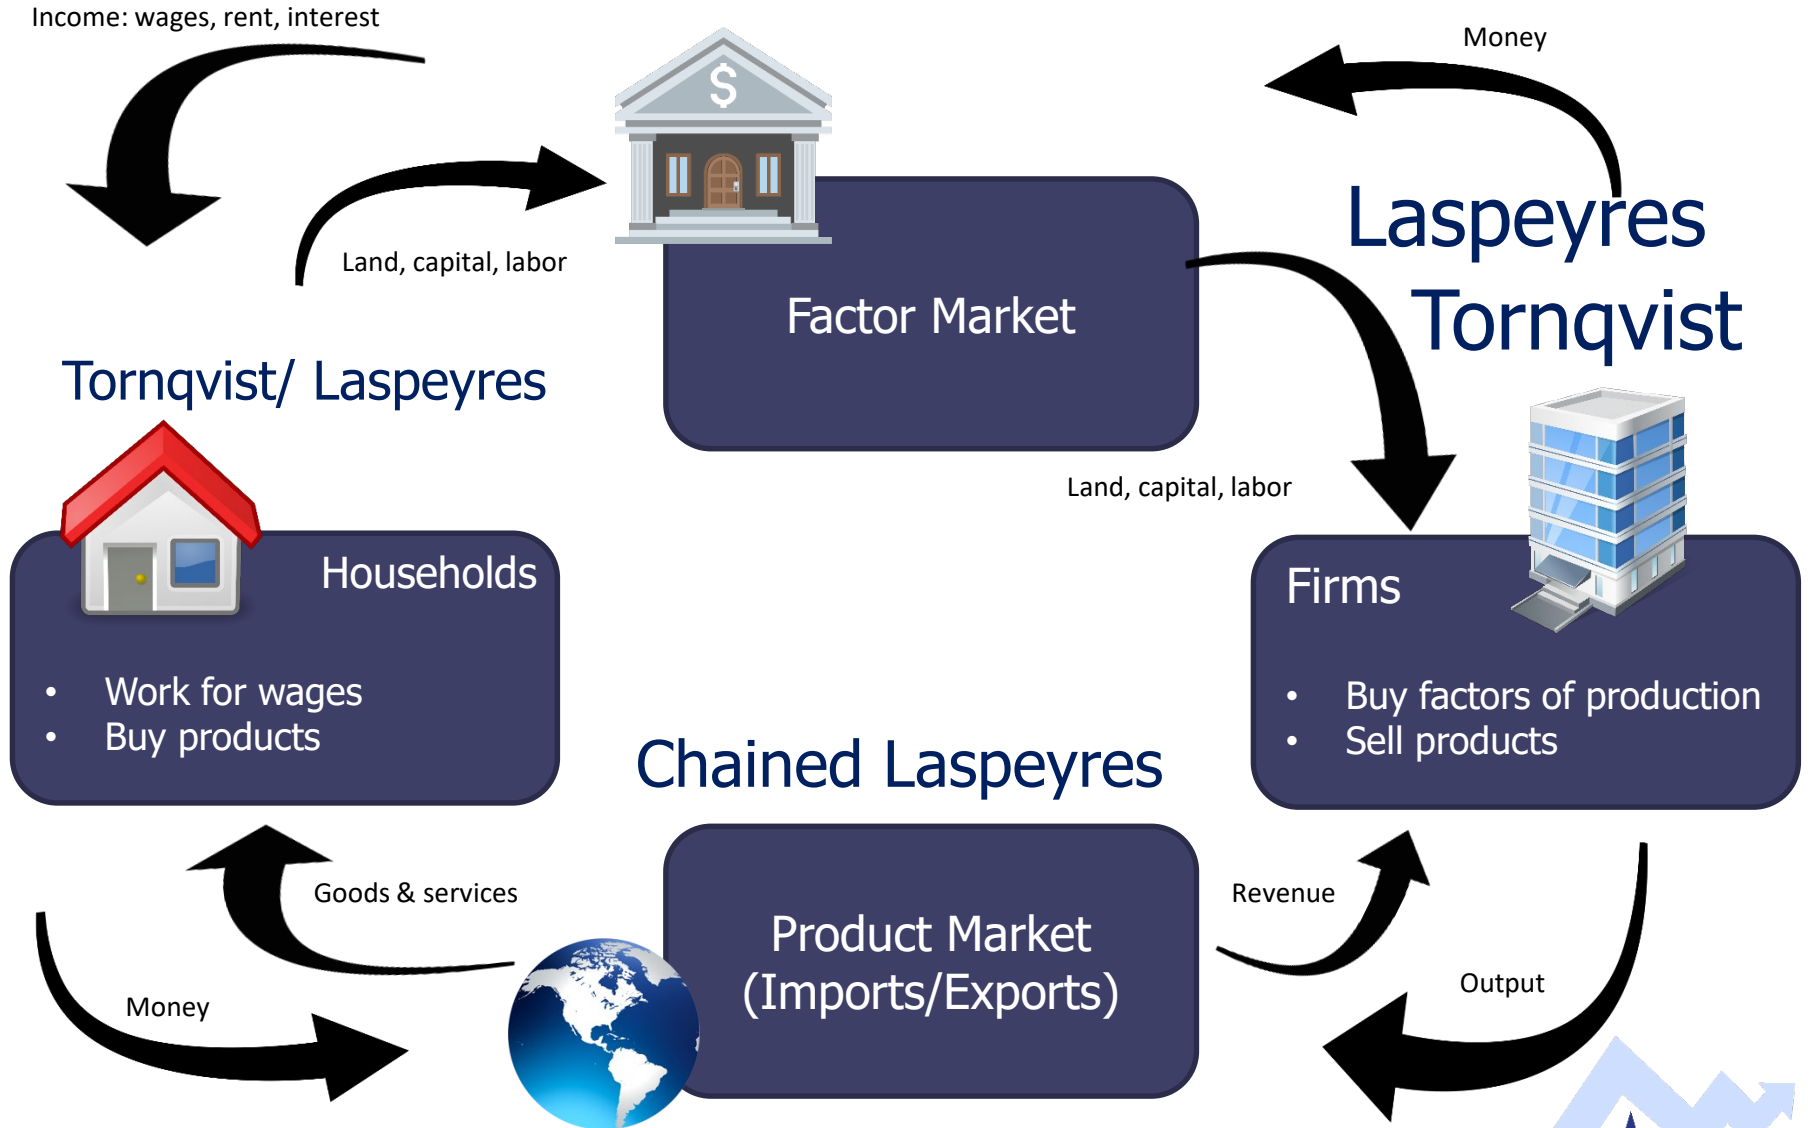

Economic Flows

Income: wages, rent, interest

Economic Flows

Common Index formulas

Laspeyres

$$I_L^{0 \rightarrow 1} = \frac{\sum_i q_i^0 * p_i^1}{\sum_i q_i^0 * p_i^0} = \sum_i s_i^0 * \left(\frac{p_i^1}{p_i^0} \right) \text{ where } s_i^t = \frac{p_i^t * q_i^t}{\sum_j p_j^t * q_j^t}$$

Paasche

$$I_P^{0 \rightarrow 1} = \frac{\sum_i q_i^1 * p_i^1}{\sum_i q_i^1 * p_i^0} = \left\{ \sum_i s_i^1 * \left(\frac{p_i^1}{p_i^0} \right)^{-1} \right\}^{-1}$$

Common Index formulas

Fisher

$$I_F^{0 \rightarrow 1} = \sqrt{I_L^{0 \rightarrow 1} * I_P^{0 \rightarrow 1}}$$

Tornqvist

$$I_T^{0 \rightarrow 1} = \sqrt{\prod_i \left(\frac{p_i^1}{p_i^0}\right)^{s_i^0} * \prod_i \left(\frac{p_i^1}{p_i^0}\right)^{s_i^1}} = \prod_i \left(\frac{p_i^1}{p_i^0}\right)^{(s_i^0 + s_i^1)/2}$$

These are “chained” consecutively.

Tornqvist step-by-step

Quantity:

Aggregating multiple categories into one

Real dollar Production (based 2009)	2007	2008	2009	2010	2011	2012

Common Index formulas

How the Tornqvist Index is used in productivity theory

How it's used

- Aggregating to create an industry sector
- Combine multiple categories in a particular industry(s)
- Problematic cases for the Tornqvist

Aggregating to create an industry sector

Literature on the theory of index numbers has shown that Tornqvist has desirable properties.

- Exact index for translog structure of production
- Used to combine indices of inputs (Capital and Labor)

*Dean, Harper, Sherwood (1996) page 185

Combine multiple categories in a particular industry(s)

For the same reasons mentioned before the Tornqvist index is used.

Relevant theory only uses growth rates of quantities and prices.

How the Tornqvist Index is used in productivity theory

Demonstrations

1. Information capital measure
2. Manufacturing sector aggregation

R package Dependencies

`dplyr`

`tidyr`

R package Dependencies

```
mutate( )  
select( )  
arrange( )  
group_by( )  
rename( )  
Left_join( )  
Inner_join( )
```

```
gather( )
```

R package Dependencies

`mutate()` - create new variables
`select()` - keep certain variables
`arrange()` - sort data frames
`group_by()` - group data frame for
following calculations
`rename()` - rename variables
`left_join()` - merge tables toward
the left most data frame
`inner_join()` - returns everything

`gather()` - transpose

R package Dependencies

```
mutate(df, new_var= old_var*9 )
```

```
select(df, var1, var2, var3)
```

```
arrange(df, var1, var2, var3)
```

```
by_cyl<-group_by(df, var1 )
```

```
by_cyl2<-summarize(by_cyl, ...)
```

```
rename(df, var_newname=var1)
```

```
left_join(var1, var2, by=key)
```

```
inner_join(var1, var2, by=key)
```

R package Dependencies

```
gather(df, key="key_var" , value )
```

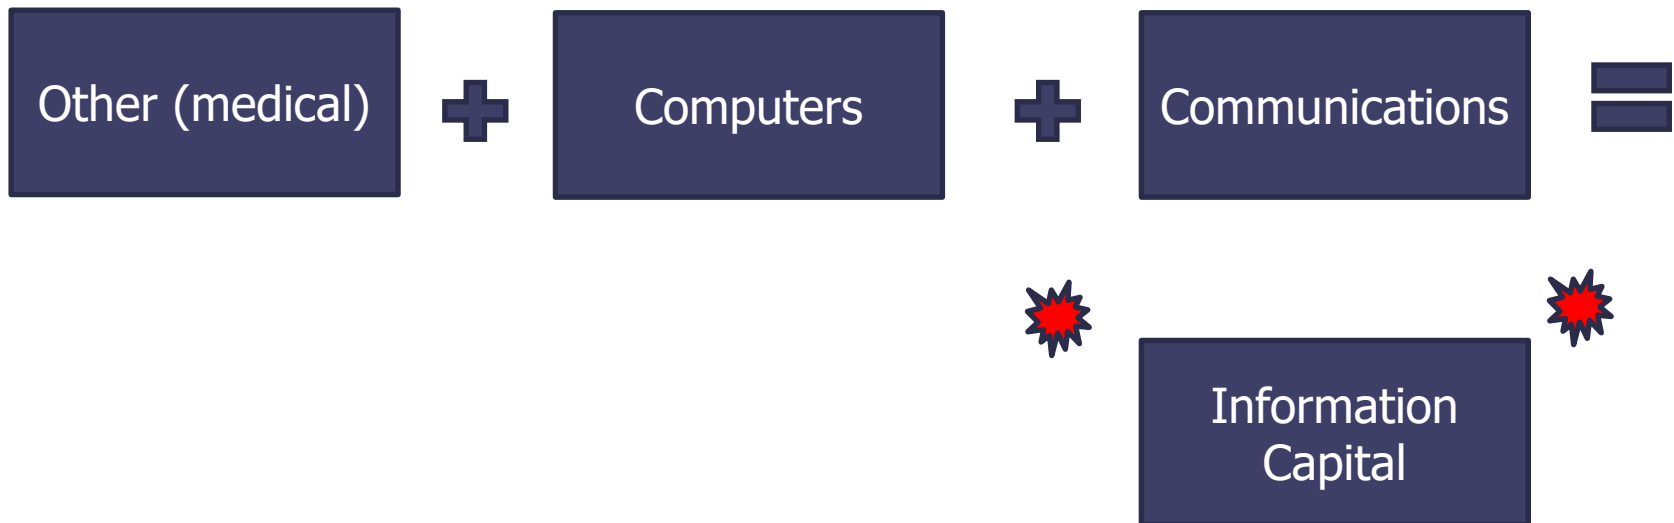

YEAR	Red	Green
2010	50	80
2011	40	100

VAR	2010	2011
Red	50	40
Green	80	100

Information capital measure

Aggregate multiple measures for each industry to form a new information capital time series.

`tornqvist_index_m (quantity_var, cost_var, base_year)`

`tornqvist_index_m (quantity_var, cost_var, base_year)`

Manufacturing sector aggregation

Aggregate multiple different industries (NAICS) into one super-sector.

```
tornqvist_index_ind(input,base_year,NAME)
```

```
tornqvist_index_ind(input,base_year,NAME)
```

Pre-processing

```
input<-select(df, ce , qex, naics, year)
```

```

Creative learning

Why did the statisticians and economists go to the forest?

Limitation of Tornqvist

Equation gives unstable values when

- data has zeros
- missing values
- extreme growth rates from period to period

A quantity near zero, even with a small expenditure share, can greatly affect the index.

General recommendations for hard cases

- Check data tables for zeros or extreme growth rates
- Replace outliers or put cap on growth rates
- Address mainly with *imputation*, *smoothing* and/or *merging* of items
- Avoid imputing hard-coded figures such as 0.01 if possible
- After replacing a value, consider rescaling so totals stay the same

Functions to smooth/merge

- One approach is to merge an item with extreme growth rates into a larger group
- Or, user makes imputation based on knowing the context of the data.
- If neither, these functions now under development, can test an input series to see whether an extreme growth rate (like 20:1) is exceeded and adjust outliers minimally to limit those growth rates.

```
steepstest(vector, .05, 20)
```

```
steeplimit(vector, .05, 20)
```
